To compute bearing loads, the forces which act on the shaft being supported by the bearing must be determined. Loads which act on the shaft and its related parts include dead load of the rotator, load produced when the machine performs work, and load produced by transmission of dynamic force. These can theoretically be mathematically calculated, but calculation is difficult in many cases.

A method of calculating loads that act upon shafts that convey dynamic force, which is the primary application of bearings, is provided herein.

4.1 Load acting on shafts

4.1.1 Load factor

There are many instances where the actual operational shaft load is much greater than the theoretically calculated load, due to machine vibration and/or shock. This actual shaft load can be found by using formula (4.1).

\[ K = f_w \cdot K_c \]  \hspace{1cm} (4.1)

where,
\( K \): Actual shaft load \( \text{N} \{\text{kgf}\} \)
\( f_w \): Load factor \((\text{Table 4.1})\)
\( K_c \): Theoretically calculated value \( \text{N} \{\text{kgf}\} \)

4.1.2 Gear load

The loads operating on gears can be divided into three main types according to the direction in which the load is applied; i.e. tangential \( (K_t) \), radial \( (K_r) \), and axial \( (K_a) \). The magnitude and direction of these loads differ according to the types of gears involved. The load calculation methods given herein are for two general-use gear and shaft arrangements: parallel shaft gears, and cross shaft gears.

(1) Loads acting on parallel shaft gears

The forces acting on spur gears and helical gears are depicted in Figs. 4.1, 4.2, and 4.3. The load magnitude can be found by using or formulas (4.2), through (4.5).

\[ K_t = \frac{19.1 \times 10^6 \cdot H}{D_p \cdot n} \hspace{0.5cm} \text{N} \]  \hspace{1cm} (4.2)

\[ = \frac{1.95 \times 10^6 \cdot H}{D_p \cdot n} \hspace{0.5cm} \{\text{kgf}\} \]  \hspace{1cm} (4.2)

\[ K_r = \sqrt{K_t^2 + K_s^2} \]  \hspace{1cm} (4.4)

\[ K_a = K_t \cdot \tan \beta \]  \hspace{1cm} (4.5)

where,
\( K_t \): Tangential gear load (tangential force), \( \text{N} \{\text{kgf}\} \)
\( K_r \): Radial gear load (separating force), \( \text{N} \{\text{kgf}\} \)
\( K_a \): Right angle shaft load (resultant force of tangential force and separating force), \( \text{N} \{\text{kgf}\} \)
\( H \): Transmission force, \( \text{kW} \)
\( n \): Rotational speed, \( \text{min}^{-1} \)
\( D_p \): Gear pitch circle diameter, \( \text{mm} \)
\( \alpha \): Gear pressure angle, \( \text{deg} \)
\( \beta \): Gear helix angle, \( \text{deg} \)

Because the actual gear load also contains vibrations and shock loads as well, the theoretical load obtained by the above formula should also be adjusted by the gear factor \( f_c \) as shown in Table 4.2.
(2) Loads acting on cross shafts

Gear loads acting on straight tooth bevel gears and spiral bevel gears on cross shafts are shown in Figs. 4.4 and 4.5. The calculation methods for these gear loads are shown in Table 4.3. Herein, to calculate gear loads for straight bevel gears, the helix angle $\beta = 0$.

The symbols and units used in Table 4.3 are as follows:

- $K_t$: Tangential gear load (tangential force), N {kgf}
- $K_s$: Radial gear load (separating force), N {kgf}
- $K_a$: Parallel shaft load (axial load), N {kgf}
- $H$: Transmission force, kW
- $n$: Rotational speed, min\(^{-1}\)
- $D_{pm}$: Mean pitch circle diameter, mm
- $\alpha$: Gear pressure angle, deg
- $\beta$: Helix angle, deg
- $\delta$: Pitch cone angle, deg

Because the two shafts intersect, the relationship of pinion and gear load is as follows:

$$K_{sp} = K_{ag} \cdots \cdots (4.6)$$

$$K_{ap} = K_{sg} \cdots \cdots (4.7)$$

where,

- $K_{sp}$, $K_{sg}$: Pinion and gear separating force, N {kgf}
- $K_{ap}$, $K_{ag}$: Pinion and gear axial load, N {kgf}

For spiral bevel gears, the direction of the load varies depending on the direction of the helix angle, the direction of rotation, and which side is the driving side or the driven side. The directions for the separating force ($K_s$) and axial load ($K_a$) shown in Fig. 4.5 are positive directions. The direction of rotation and the helix angle direction are defined as viewed from the large end of the gear. The gear rotation direction in Fig. 4.5 is assumed to be clockwise (right).

</tbody>
</table>
4.1.3 Chain / belt shaft load

The tangential loads on sprockets or pulleys when power (load) is transmitted by means of chains or belts can be calculated by formula (4.8).

\[
K_t = \frac{19.1 \times 10^6 \cdot H}{D_p \cdot n} \quad \text{N} \\
= \frac{1.95 \times 10^6 \cdot H}{D_p \cdot n} \quad \text{[kgf]} \quad (4.8)
\]

where,

- \(K_t\): Sprocket/pulley tangential load, N (kgf)
- \(H\): Transmitted force, kW
- \(D_p\): Sprocket/pulley pitch diameter, mm

For belt drives, an initial tension is applied to give sufficient constant operating tension on the belt and pulley. Taking this tension into account, the radial loads acting on the pulley are expressed by formula (4.9). For chain drives, the same formula can also be used if vibrations and shock loads are taken into consideration.

\[
K_r = f_b \cdot K_t \quad (4.9)
\]

where,

- \(K_r\): Sprocket or pulley radial load, N (kgf)
- \(f_b\): Chain or belt factor (Table 4.4)

**Table 4.4 Chain or belt factor \(f_b\)**

4.2 Bearing load distribution

For shafting, the static tension is considered to be supported by the bearings, and any loads acting on the shafts are distributed to the bearings.

For example, in the gear shaft assembly depicted in Fig. 4.7, the applied bearing loads can be found by using formulas (4.10) and (4.11).

\[
F_{ra} = \frac{a + b}{b} F_1 + \frac{d}{c + d} F_2 \quad (4.10)
\]

\[
F_{rb} = - \frac{a}{b} F_1 + \frac{c}{c + d} F_2 \quad (4.11)
\]

where,

- \(F_{ra}\): Radial load on bearing A, N (kgf)
- \(F_{rb}\): Radial load on bearing B, N (kgf)
- \(F_1, F_2\): Radial load on shaft, N (kgf)

If directions of radial load differ, the vector sum of each respective load must be determined.
4.3 Mean load

The load on bearings used in machines under normal circumstances will, in many cases, fluctuate according to a fixed time period or planned operation schedule. The load on bearings operating under such conditions can be converted to a mean load \( F_m \), this is a load which gives bearings the same life they would have under constant operating conditions.

1) Fluctuating stepped load

The mean bearing load, \( F_m \), for stepped loads is calculated from formula (4.12). \( F_1, F_2, \ldots, F_n \) are the loads acting on the bearing; \( n_1, n_2, \ldots, n_n \) and \( t_1, t_2, \ldots, t_n \) are the bearing speeds and operating times respectively.

\[
F_m = \left[ \frac{\sum (F_i^{p} n_i t_i)}{\sum (n_i t_i)} \right]^{1/p}
\]  

(4.12)

where:

\( p = 3 \) For ball bearings

\( p = 10/3 \) For roller bearings

Fig. 4.8 Stepped load

2) Continuously fluctuating load

Where it is possible to express the function \( F(t) \) in terms of load cycle \( t_0 \) and time \( t \), the mean load is found by using formula (4.13).

\[
F_m = \left[ \frac{1}{t_0} \int_{t_0}^{t} F(t)^p \, dt \right]^{1/p}
\]  

(4.13)

where:

\( p = 3 \) For ball bearings

\( p = 10/3 \) For roller bearings

Fig. 4.9 Load that fluctuated as function of time

3) Linear fluctuating load

The mean load, \( F_{lin} \), can be approximated by formula (4.14).

\[
F_{lin} = \frac{F_{min} + 2F_{max}}{3}
\]  

(4.14)

Fig. 4.10 Linear fluctuating load

4) Sinusoidal fluctuating load

The mean load, \( F_{sin} \), can be approximated by formulas (4.15) and (4.16).

case (a) \( F_{sin} = 0.75F_{max} \)  

(4.15)

case (b) \( F_{sin} = 0.65F_{max} \)  

(4.16)

Fig. 4.11 Sinusoidal variable load
4.4 Equivalent load

4.4.1 Dynamic equivalent load
When both dynamic radial loads and dynamic axial loads act on a bearing at the same time, the hypothetical load acting on the center of the bearing which gives the bearings the same life as if they had only a radial load or only an axial load is called the dynamic equivalent load.

For radial bearings, this load is expressed as pure radial load and is called the dynamic equivalent radial load. For thrust bearings, it is expressed as pure axial load, and is called the dynamic equivalent axial load.

(1) Dynamic equivalent radial load
The dynamic equivalent radial load is expressed by formula (4.17).

\[ P_r = X F_r + Y F_a \]  \hspace{1cm} (4.17)

where,
- \( P_r \): Dynamic equivalent radial load, N [kgf]
- \( F_r \): Actual radial load, N [kgf]
- \( F_a \): Actual axial load, N [kgf]
- \( X \): Radial load factor
- \( Y \): Axial load factor

The values for \( X \) and \( Y \) are listed in the bearing tables.

(2) Dynamic equivalent axial load
As a rule, standard thrust bearings with a contact angle of 90° cannot carry radial loads. However, self-aligning thrust roller bearings can accept some radial load. The dynamic equivalent radial load for these bearings is given in formula (4.18).

\[ P_o = F_a + 1.2 F_r \] \hspace{1cm} (4.18)

where,
- \( P_o \): Dynamic equivalent axial load, N [kgf]
- \( F_a \): Actual axial load, N [kgf]
- \( F_r \): Actual radial load, N [kgf]

Provided that \( F_r / F_a < 0.55 \) only.

4.4.2 Static equivalent load
The static equivalent load is a hypothetical load which would cause the same total permanent deformation at the most heavily stressed contact point between the rolling elements and the raceway as under actual load conditions; that is when both static radial loads and static axial loads are simultaneously applied to the bearing.

For radial bearings this hypothetical load refers to pure radial loads, and for thrust bearings it refers to pure centric axial loads. These loads are designated static equivalent radial loads and static equivalent axial loads respectively.

(1) Static equivalent radial load
For radial bearings the static equivalent radial load can be found by using formula (4.19) or (4.20). The greater of the two resultant values is always taken for \( P_o \).

\[ P_o = X_o F_r + Y_o F_a \] \hspace{1cm} (4.19)
\[ P_o = F_r \] \hspace{1cm} (4.20)

where,
- \( P_o \): Static equivalent radial load, N [kgf]
- \( F_r \): Actual radial load, N [kgf]
- \( F_a \): Actual axial load, N [kgf]
- \( X_o \): Static radial load factor
- \( Y_o \): Static axial load factor

The values for \( X_o \) and \( Y_o \) are given in the respective bearing tables.

(2) Static equivalent axial load
For spherical thrust bearings the static equivalent axial load is expressed by formula (4.21).

\[ P_o = F_a + 2.7 F_r \] \hspace{1cm} (4.21)

where,
- \( P_o \): Static equivalent axial load, N [kgf]
- \( F_a \): Actual axial load, N [kgf]
- \( F_r \): Actual radial load, N [kgf]

Provided that \( F_r / F_a < 0.55 \) only.

4.4.3 Load calculation for angular contact ball bearings and tapered roller bearings
For angular contact ball bearings and tapered roller bearings the pressure cone apex (load center) is located as shown in Fig. 4.12, and their values are listed in the bearing tables.

When radial loads act on these types of bearings the component force is induced in the axial direction. For this reason, these bearings are used in pairs. For load calculation this component force must be taken into consideration and is expressed by formula (4.22).

\[ F_a = \frac{0.5 F_r}{Y} \] \hspace{1cm} (4.22)

where,
- \( F_a \): Axial component force, N [kgf]
- \( F_r \): Radial load, N [kgf]
- \( Y \): Axial load factor

The dynamic equivalent radial loads for these bearing pairs are given in Table 4.5.

2. Radial forces in the opposite direction to the arrow in the above illustration are also regarded as positive.
4.5 Bearing rating life and load calculation examples

In the examples given in this section, for the purpose of calculation, all hypothetical load factors as well as all calculated load factors may be presumed to be included in the resultant load values.

(Example 1)
What is the rating life in hours of operation \( L_{10h} \) for deep groove ball bearing 6208 operating at rotational speed \( n = 650 \text{ min}^{-1} \), with a radial load \( F_r \) of 3.2 kN \( (326 \text{ kgf}) \) ?

From formula (4.17) the dynamic equivalent radial load:

\[
P_r = F_r = 3.2 \text{ kN \{326 kgf\}}
\]

Basic dynamic load rating \( C_r \) for bearing 6208 given on page B-12 is 29.1 kN \( (2970 \text{ kgf}) \), ball bearing speed factor \( f_n \) relative to rotational speed \( n = 650 \text{ min}^{-1} \) from Fig. 3.1 is \( f_n = 0.37 \). Thus life factor \( f_h \) from formula (3.5) is:

\[
f_h = f_n \frac{C_r}{P_r} = 0.37 \times \frac{29.1}{3.2} = 3.36
\]

Therefore, with \( f_h = 3.36 \) from Fig. 3.1 the rated life, \( L_{10h} \), is approximately 19,000 hours.

(Example 2)
What is the life rating \( L_{10h} \) for the same bearing and conditions as in Example 1, but with an additional axial load \( F_a \) of 1.8 kN \( (184 \text{ kgf}) \) ?

To find the dynamic equivalent radial load value for \( P_r \), the radial load factor \( X \) and axial load factor \( Y \) are used. Basic static load rating \( C_{or} \) for bearing 6208 given on page B-12 is 17.8 kN \( (1820 \text{ kgf}) \) and \( f_o \) is 14.0. Therefore:

\[
f_o \cdot F_a = \frac{14 \times 1.8}{17.8} = 1.42
\]

Calculating by the proportional interpolation method given on page B-13, \( e = 0.30 \).

For the operating radial load and axial load:

\[
\frac{F_a}{F_r} = \frac{1.8}{3.2} = 0.56 > e = 0.30
\]

From page B-13 \( X = 0.56 \) and \( Y = 1.44 \), and from formula (4.17) the equivalent radial load, \( P_s \), is:

\[
P_s = XP_r + YF_a = 0.56 \times 3.2 + 1.43 \times 1.8 = 4.38 \text{ kN \{447kgf\}}
\]

From Fig. 3.1 and formula (3.1) the life factor, \( f_h \), is:

\[
f_h = f_n \frac{C_r}{P_r} = 0.37 \times \frac{29.1}{4.38} = 2.46
\]

Therefore, with life factor \( f_h = 2.46 \), from Fig. 3.1 the rated life, \( L_{10h} \), is approximately 7,500 hours.

(Example 3)
Determine the optimum model number for a cylindrical roller bearing operating at the rotational speed \( n = 450 \text{ min}^{-1} \), with a radial load \( F_r \) of 200 kN \( (20,400 \text{ kgf}) \), and which must have a life \( L_{10h} \) of over 20,000 hours.

From Fig. 3.1 the life factor, \( f_h = 3.02 \) \( (L_{10h} \text{ at } 20,000) \), and the speed factor, \( f_n = 0.46 \) \( (n = 450 \text{ min}^{-1}) \). To find the required basic dynamic load rating, \( C_r \), formula (3.1) is used.

\[
C_r = \frac{f_s}{f_s} \frac{P_r}{f_s} \times 0.46 \times 200
\]

\[
= 1,313 \text{ kN \{134,000kgf\}}
\]

From page B-106, the smallest bearing that fulfills all the requirements is NU2336 \( (C_r = 1,380 \text{ kN \{141,000kgf\}}) \).
Therefore: $a_2 = 1.4$ (4T-tapered roller bearings shown in B-144)

$$L_{n1} = 13,200 \times a_2 = 13,200 \times 1.4 = 18,480 \text{ hour}$$

$$L_{n2} = 11,600 \times a_2 = 11,600 \times 1.4 = 16,240 \text{ hour}$$

The combined bearing life, $L_n$, from formula (3.3) is:

$$L_n = \frac{1}{\left( \frac{1}{L_n} + \frac{1}{L_{n1}} \right)^{1/e}}$$

$$= \frac{1}{\left( \frac{1}{18,480^{1/8}} + \frac{1}{16,240^{1/8}} \right)^{8/9}}$$

$$= 9,330 \text{ hour}$$

The spur gear shown in Fig. 4.13 (pitch diameter $D_p = 150 \text{ mm}$, pressure angle $\alpha = 20^\circ$) is supported by a pair of tapered roller bearings, 4T-32206 ($C_r = 54.5 \text{ kN (5,600 kgf)}$) and 4T-32205 ($C_r = 42 \text{ kN (4300 kgf)}$).

Find rating life for each bearing when gear transfer power $H = 150 \text{ kW}$ and rotational speed $n = 2,000 \text{ min}^{-1}$.

---

**Bearings I**

(4T-32206)

**Bearings II**

(4T-32205)

---

The gear load from formulas (4.2), (4.3a) and (4.4) is:

$$K_t = \frac{19.1 \times 10^6 \times H}{D_p \cdot n} = 19.100 \times 150 \times 2,000 = 9.55 \text{ kN (974 kgf)}$$

$$K_t = K_t \cdot \tan \alpha = 9.55 \times \tan 20^\circ = 3.48 \text{ kN (355 kgf)}$$

$$K_t = \sqrt{K_t^2 + K_s^2} = \sqrt{9.55^2 + 3.48^2} = 10.16 \text{ kN (1,040 kgf)}$$

The radial loads for bearings I and II are:

$$F_{1i} = \frac{100}{170} K_t = \frac{100}{170} \times 10.16 = 5.98 \text{ kN (610 kgf)}$$

$$F_{2i} = \frac{70}{170} K_t = \frac{70}{170} \times 10.16 = 4.18 \text{ kN (426 kgf)}$$

$$\frac{0.5 F_{1i}}{Y_1} = 1.87 > \frac{0.5 F_{1i}}{Y_2} = 1.25$$

From Table 4.5, equivalent radial load:

$$P_{1i} = F_{1i} = 5.98 \text{ kN (610 kgf)}$$

$$P_{2i} = X F_{1i} + Y_2 \frac{0.5 F_{1i}}{Y_1}$$

$$= 0.4 \times 4.18 + 1.67 \times 1.87 = 4.79 \text{ kN (489 kgf)}$$

From formula (3.5) and Fig. 3.1 the life factor, $f_h$, for each bearing is:

$$f_{h1} = f_h \frac{C_{r1}}{P_{1i}} = 0.293 \times 54.5 / 5.98 = 2.67$$

$$f_{h2} = f_h \frac{C_{r2}}{P_{2i}} = 0.293 \times 42.0 / 4.79 = 2.57$$

---

(Example 4)

The spur gear shown in Fig. 4.13 (pitch diameter $D_p = 150 \text{ mm}$, pressure angle $\alpha = 20^\circ$) is supported by a pair of tapered roller bearings, 4T-32206 ($C_r = 54.5 \text{ kN (5,600 kgf)}$) and 4T-32205 ($C_r = 42 \text{ kN (4300 kgf)}$).

Find rating life for each bearing when gear transfer power $H = 150 \text{ kW}$ and rotational speed $n = 2,000 \text{ min}^{-1}$.
Bearing Load Calculation

(Example 5)
Find the mean load for spherical roller bearing 23932 ($L_a = 320 \text{kN} \ (33,000 \text{kgf})$) when operated under the fluctuating conditions shown in Table 4.6.

From formula (4.12) the mean load, $F_m$, is found by using formula (4.17) and shown in Table 4.7.

Because all the values for $F_m$ and $F_a$ from the bearing tables are greater than $F_m/F_a > c = 0.18$, $X = 0.67$, $Y_2 = 5.50$.

$$P_a = XF_m + Y_2F_a = 0.67F_m + 5.50F_a$$

From formula (4.12) the mean load, $F_m$, is:

$$F_m = \left( \frac{\sum (P_{ai}^{10/3} \cdot \phi_i)}{\sum (\phi_i)} \right)^{3/10} = 48.1 \text{kN} \ (4,906 \text{kgf})$$

The equivalent radial load, $P_a$, for each operating condition is found by using formula (4.17) and shown in Table 4.7.

(Example 6)
Find the threshold values for rating life time and allowable axial load when cylindrical roller bearing NUP312 is used under the following conditions:
Provided that intermittent axial load and oil lubricant.

Radial load $F_r = 10 \text{kN} \ (1,020 \text{kgf})$

Rotational speed $n = 2,000 \text{ min}^{-1}$

Radial load is:

$$P_a = F_r = 10 \text{kN} \ (1,020 \text{kgf})$$

The speed factor of cylindrical roller bearing, $f_n$, at $n = 2,000 \text{ min}^{-1}$, from Table 3.1

$$f_n = \left( \frac{33.3}{2,000} \right)^{3/10} = 0.293$$

The life factor, $f_h$, from formula (3.4)

$$f_h = 0.293 \times \left( \frac{124}{10} \right) = 3.63$$

Therefore the basic rated life, $L_{10}$, from Table 3.1

$$L_{10} = 500 \times 3.63^{10/3} \approx 37,000$$

And next, allowable axial load of cylindrical roller bearing is shown in page B-93.

In formula (1) on page B-93, based on NUP312 from Table 4 on page B-93, $k = 0.065$.

$$d_b = \frac{(60 + 130)/2} = 95 \text{mm}, \quad n = 2,000 \text{ min}^{-1}$$

Take into consideration that intermittent axial load.

$$d_b \cdot n \times 10^4 = 95 \times 10^4$$

In Fig. 1 on page B-93, $d_b \cdot n = 19 \times 10^4$. In the case of intermittent axial load, allowable surface pressure at the lip $P_1 = 40 \text{ MPa}$.

Therefore the allowable axial load, $P_a$, following

$$P_a = 0.065 \times 60^4 \times 40 = 9,360 \text{N} \ (954 \text{kgf})$$

Based on Table 4 of page B-93, it is within the limits of $F_{a \text{max}} < 0.4 \times 10,000 = 4,000 \text{N}$. Therefore $P_1 < 4,000 \text{N} \ (408 \text{kgf})$.
